Understanding Back Propagation

What is Back Propagation?

Back propagation (short for "backward propagation of errors") is a supervised learning algorithm used to train multi-layer neural networks. It involves propagating the error from the output layer back through the network to update the weights iteratively, minimizing the difference between predicted outputs and actual targets.

Key Components of Back Propagation

- **Neural Network Architecture:** Consists of input, hidden, and output layers with interconnected neurons.
- **Weights and Biases:** Parameters that are adjusted during training to improve network performance.
- **Activation Functions:** Functions like sigmoid, tanh, or ReLU that introduce non-linearity.
- **Error Function:** Typically mean squared error (MSE), measuring the difference between predicted and actual values.
- **Learning Rate:** Determines the size of weight updates during training.

The Back Propagation Process

- **Forward Pass:** Inputs are fed through the network to generate an output.
- **Error Calculation:** The difference between the network output and the target is computed.
- **Backward Pass (Error Propagation):** Errors are propagated back through the network to

compute gradients.

- **Weights Update:** Using the gradients, weights are adjusted to minimize the error.

Implementing Back Propagation in MATLAB

Setting Up the Data

Before implementing the algorithm, you need to prepare your data. For simplicity, let's consider a small dataset for XOR problem:

```
```matlab

% Input data (XOR problem)

inputs = [0 0; 0 1; 1 0; 1 1]';

targets = [0 1 1 0]; % Corresponding targets

```
```

Designing the Neural Network Structure

A simple neural network for XOR typically includes:

- 2 input neurons
- 1 hidden layer with 2 neurons
- 1 output neuron

Define initial weights and biases randomly:

```
```matlab

% Initialize weights and biases

% Input to hidden layer

W_input_hidden = rand(2,2)/2 - 1; % 2x2 matrix

b_hidden = rand(2,1)/2 - 1; % 2x1 vector
```

```
% Hidden to output layer
```

```
W_hidden_output = rand(1,2)/2 - 1; % 1x2 matrix
```

```
b_output = rand(1,1)/2 - 1; % scalar
```

```
...
```

## Activation Function and Its Derivative

For the XOR problem, sigmoid activation is commonly used:

```
```matlab
```

```
% Sigmoid function
```

```
sigmoid = @(x) 1./(1 + exp(-x));
```

```
% Derivative of sigmoid
```

```
sigmoid_derivative = @(x) sigmoid(x).*(1 - sigmoid(x));
```

```
...
```

Training Loop with Back Propagation

Implement the training process over multiple epochs:

```
```matlab
```

```
% Set training parameters
```

```
learning_rate = 0.5;
```

```
epochs = 10000;
```

```
for i = 1:epochs
```

```
for j = 1:size(inputs,2)
```

```
% Forward pass
```

```
input = inputs(:,j);

% Hidden layer

hidden_input = W_input_hidden input + b_hidden;

hidden_output = sigmoid(hidden_input);

% Output layer

final_input = W_hidden_output hidden_output + b_output;

output = sigmoid(final_input);

% Calculate error

target = targets(j);

error = target - output;

% Backward pass

delta_output = error sigmoid_derivative(final_input);

delta_hidden = (W_hidden_output' delta_output) . sigmoid_derivative(hidden_input);

% Update weights and biases

W_hidden_output = W_hidden_output + learning_rate delta_output hidden_output';

b_output = b_output + learning_rate delta_output;

W_input_hidden = W_input_hidden + learning_rate delta_hidden input';

b_hidden = b_hidden + learning_rate delta_hidden;

end

end

...
```

## Evaluating the Trained Neural Network

After training, test the network to see how well it performs:

```
```matlab

for j = 1:size(inputs,2)

input = inputs(:,j);

% Forward pass

hidden_input = W_input_hidden input + b_hidden;

hidden_output = sigmoid(hidden_input);

final_input = W_hidden_output hidden_output + b_output;

output = sigmoid(final_input);

fprintf('Input: [%d %d], Predicted Output: %.4f\n', input(1), input(2), output);

end

```
```

Expected outputs should be close to the targets (0 or 1), demonstrating successful learning.

## Advanced Tips for Back Propagation in MATLAB

### Using MATLAB's Neural Network Toolbox

Matlab provides a robust Neural Network Toolbox which simplifies back propagation training with functions like `train`, `patternnet`, etc. Example:

```

```
net = train(net, inputs, targets);
```

```
outputs = net(inputs);
```

```
disp(outputs);
```

```
...
```

Back Propagation Using MATLAB Code: A Comprehensive Guide

Back propagation remains one of the foundational algorithms for training artificial neural networks (ANNs). Its efficiency and simplicity have made it the go-to method for adjusting weights in multi-layer networks. This detailed review delves into the mechanics of back propagation, illustrating

how to implement it effectively using MATLAB?an environment favored by many researchers and practitioners for its mathematical prowess and ease of visualization.

Understanding the Fundamentals of Back Propagation

Before diving into MATLAB code, it's crucial to understand the core concepts underpinning back propagation.

What Is Back Propagation?

Back propagation is a supervised learning algorithm designed to minimize the error in neural networks by iteratively updating weights through gradient descent. It propagates the error backward from the output layer to the input layer, allowing each weight to be adjusted proportionally to its contribution to the output error.

Key Components of Back Propagation

- Neural Network Architecture: Consists of input, hidden, and output layers with interconnected neurons.
- Activation Function: Non-linear functions like sigmoid, tanh, or ReLU that introduce non-linearity.
- Error Function: Usually Mean Squared Error (MSE) that quantifies the difference between predicted and actual outputs.
- Learning Rate (α): Determines the size of weight updates.
- Weight Initialization: Starting weights, typically small random values to break symmetry.

Mathematical Foundations

The core process involves two phases:

- Forward Propagation: Inputs are processed through the network to generate an output.
- Backward Propagation: The error is calculated and propagated backward, updating weights via gradient descent.

The weight update rule for a weight w_{ij} connecting neuron i to neuron j :

$$w_{ij}^{\text{new}} = w_{ij}^{\text{old}} - \alpha \frac{\partial E}{\partial w_{ij}}$$

∇

where ∇E is the error function.

The partial derivative $\left(\frac{\partial E}{\partial w_{ij}} \right)$ is computed using the chain rule, which involves derivatives of the activation functions.

Designing a Neural Network in MATLAB

Creating an effective back propagation algorithm in MATLAB involves several steps:

1. Network Architecture Specification

Define:

- Number of input neurons
- Number of hidden neurons
- Number of output neurons

Example:

```
```matlab
```

```
input_dim = 2; % Input features
```

```
hidden_dim = 3; % Hidden layer neurons
```

```
output_dim = 1; % Output neuron
```

```
```
```

2. Initialization of Weights and Biases

Random initialization helps break symmetry:

```
```matlab
```

```
% Initialize weights with small random values
```

```
W_input_hidden = randn(input_dim, hidden_dim) * 0.1;
```

```
W_hidden_output = randn(hidden_dim, output_dim) 0.1;
```

```
% Initialize biases
```

```
b_hidden = zeros(1, hidden_dim);
```

```
b_output = zeros(1, output_dim);
```

```
...
```

### 3. Activation Functions

Common choices include sigmoid:

```
```matlab
```

```
sigmoid = @(x) 1 ./ (1 + exp(-x));
```

```
dsigmoid = @(x) sigmoid(x) . (1 - sigmoid(x));
```

```
...
```

Implementing the Back Propagation Algorithm in MATLAB

Here's a step-by-step outline:

1. Forward Pass

Calculate activations for hidden and output layers:

```
```matlab
```

```
% Inputs
```

```
X = [x1, x2]; % Sample input
```

```
% Hidden layer
```

```
hidden_input = X W_input_hidden + b_hidden;
```

```
hidden_output = sigmoid(hidden_input);
```

% Output layer

```
final_input = hidden_output W_hidden_output + b_output;
```

```
output = sigmoid(final_input);
```

```
...
```

## 2. Error Calculation

For supervised learning with target  $(T)$ :

```
```matlab
```

```
error = T - output;
```

```
% For mean squared error
```

```
E = 0.5 error^2;
```

```
...
```

3. Backward Pass (Error Propagation)

Compute deltas (errors) for each layer:

```
```matlab
```

```
delta_output = error . dsigmoid(final_input);
```

```
delta_hidden = (delta_output W_hidden_output') . dsigmoid(hidden_input);
```

```
...
```

## 4. Updating the Weights and Biases

Adjust weights using the calculated deltas:

```
```matlab
```

```
learning_rate = 0.1;
```

```
% Update weights
```

```
W_hidden_output = W_hidden_output + (hidden_output' delta_output) learning_rate;
```

```
W_input_hidden = W_input_hidden + (X' delta_hidden) learning_rate;
```

```
% Update biases
```

```
b_output = b_output + delta_output learning_rate;
```

```
b_hidden = b_hidden + delta_hidden learning_rate;
```

```
...
```

Full MATLAB Code for a Single Epoch

Here's a complete example assuming a single input sample:

```
```matlab
```

```
% Initialize parameters
```

```
input_dim = 2;
```

```
hidden_dim = 3;
```

```
output_dim = 1;
```

```
% Random initialization
```

```
W_input_hidden = randn(input_dim, hidden_dim) 0.1;
```

```
W_hidden_output = randn(hidden_dim, output_dim) 0.1;
```

```
b_hidden = zeros(1, hidden_dim);
```

```
b_output = zeros(1, output_dim);
```

```
% Sample input and target
```

```
X = [0.5, -0.3];
```

```
T = 1; % Target output

% Activation functions

sigmoid = @(x) 1 ./ (1 + exp(-x));

dsigmoid = @(x) sigmoid(x) . (1 - sigmoid(x));

% Forward pass

hidden_input = X W_input_hidden + b_hidden;

hidden_output = sigmoid(hidden_input);

final_input = hidden_output W_hidden_output + b_output;

output = sigmoid(final_input);

% Error calculation

error = T - output;

E = 0.5 error^2;

% Backward pass

delta_output = error . dsigmoid(final_input);

delta_hidden = (delta_output W_hidden_output') . dsigmoid(hidden_input);

% Update weights and biases

learning_rate = 0.1;

W_hidden_output = W_hidden_output + (hidden_output' delta_output) learning_rate;

W_input_hidden = W_input_hidden + (X' delta_hidden) learning_rate;

b_output = b_output + delta_output learning_rate;

b_hidden = b_hidden + delta_hidden learning_rate;
```

```
% Display updated weights

disp('Updated W_input_hidden:');

disp(W_input_hidden);

disp('Updated W_hidden_output:');

disp(W_hidden_output);

...
```

## Training the Neural Network: Multiple Epochs and Data

While the example above depicts a single data point, real-world training involves multiple epochs over datasets.

### Implementing a Training Loop

- Loop over all data samples
- For each sample, perform forward and backward passes
- Accumulate error to monitor convergence
- Adjust weights after each sample (stochastic gradient descent) or after all samples (batch gradient descent)

Sample structure:

```
```matlab

for epoch = 1:max_epochs

total_error = 0;

for i = 1:num_samples

% Extract sample and target

X = data(i, 1:end-1);

T = data(i, end);
```

```
% Forward pass

% ... (as above)

% Compute error

% ...

% Backward pass

% ...

% Update weights

% ...

total_error = total_error + E;

end

% Optional: display error

fprintf('Epoch %d, Error: %.4f\n', epoch, total_error);

if total_error
break;

end

end

'''
```

Enhancements and Practical Considerations

While the above provides the core framework, practical neural network training with MATLAB involves additional considerations:

- Learning Rate Scheduling: Dynamically adjusting learning rate to improve convergence.
