Introduction to Physical Nuclear Chemistry

Physical nuclear chemistry is a branch of chemistry that deals with the physical properties and behaviors of atomic nuclei. Unlike atomic chemistry, which focuses on electrons and chemical bonds, nuclear chemistry is concerned with the nucleus itself—its structure, reactions, and transformations. This field combines principles from physics and chemistry to study nuclear stability, decay mechanisms, reaction rates, and nuclear models.

Topic 12 typically covers:

- Nuclear reactions and their types
- Radioactive decay processes
- Nuclear models and theories
- Applications of nuclear chemistry in medicine and energy
- Calculations involving nuclear quantities like half-life, decay constant, and activity

Understanding these concepts is crucial for interpreting experimental data, designing nuclear systems, and applying nuclear technology safely and effectively.

Common Questions and Answers on Physical Nuclear Chemistry - Topic 12

1. What is a nuclear reaction?

A nuclear reaction involves a change in an atom's nucleus, leading to a different element or isotope. Unlike chemical reactions, which involve electrons, nuclear reactions involve the nucleus and often release or absorb significant amounts of energy.

Types of nuclear reactions include:

- Fission: Splitting of a heavy nucleus into lighter nuclei (e.g., Uranium-235 fission)
- Fusion: Combining light nuclei to form a heavier nucleus (e.g., hydrogen fusion in stars)
- Radioactive decay: Spontaneous transformation of an unstable nucleus into a more stable one

Key features:

- Involves nucleons (protons and neutrons)
- Alters atomic number and mass number
- Usually accompanied by emission of radiation (alpha, beta, gamma)

2. How is nuclear stability determined?

Nuclear stability depends on the ratio of protons to neutrons and the nuclear forces that hold the nucleus together. The binding energy per nucleon is a crucial indicator:

- Nuclei with high binding energy per nucleon are more stable.
- The belt of stability on the chart of nuclides indicates stable isotopes.
- Nuclei outside this belt tend to undergo radioactive decay to reach stability.

Factors influencing stability include:

- Proton-neutron ratio
- Nuclear shell effects
- Presence of magic numbers (2, 8, 20, 28, 50, 82, 126)

3. What are the different types of radioactive decay?

Radioactive decay is the process by which unstable nuclei emit radiation to become more stable. The main types include:

- Alpha decay: Emission of an alpha particle (2 protons + 2 neutrons)
- Beta decay: Conversion of a neutron into a proton (or vice versa), emitting beta particles (electron or positron)
- Gamma decay: Emission of gamma radiation (high-energy photons) without changing the nucleus's composition

Each decay type alters the nucleus's atomic and mass numbers accordingly:

- Alpha decay: decreases A by 4, Z by 2
- Beta decay: Z changes by ± 1 , A remains unchanged
- Gamma decay: no change in A or Z

4. How do you calculate the half-life of a radioactive isotope?

The half-life ($t_{1/2}$) is the time required for half of the radioactive nuclei in a sample to decay. It relates directly to the decay constant (λ):

Formula:

$$t_{1/2} = \frac{\ln 2}{\lambda}$$

Where:

- λ is the decay constant (probability per unit time that a nucleus decays)
- $\ln 2 \approx 0.693$

Application:

If the decay constant is known, the half-life can be easily calculated, facilitating predictions of radioactive decay over time.

5. What is the concept of nuclear binding energy?

Nuclear binding energy is the energy required to disassemble a nucleus into its constituent protons and neutrons. It quantifies the stability of a nucleus:

$$\text{Binding Energy} = (Z \cdot m_p + N \cdot m_n - M) c^2$$

where:

- Z = number of protons
- N = number of neutrons
- m_p, m_n = masses of proton and neutron
- M = actual mass of the nucleus
- c = speed of light

Higher binding energy per nucleon indicates a more stable nucleus. Peak binding energy occurs around iron (Fe), explaining why fission of heavy nuclei releases energy and fusion of light nuclei releases energy.

6. Explain the concept of nuclear transmutation.

Nuclear transmutation involves changing one element into another through nuclear reactions or decay processes. It can occur naturally (radioactive decay) or artificially (by bombarding nuclei with particles).

Methods include:

- Neutron capture: Nucleus captures a neutron, leading to a new isotope
- Particle bombardment: Using protons, alpha particles, or other ions to induce reactions
- Radioactive decay: Spontaneous transformation over time

Applications:

- Production of medical isotopes
- Nuclear waste management
- Synthesis of new elements

7. What is the significance of the mass defect?

Mass defect is the difference between the sum of the individual masses of protons and neutrons and the actual mass of the nucleus. It reflects the mass converted into binding energy:

$$\Delta m = (\sum m_{\text{nucleon}}) - M$$

This energy is responsible for nuclear stability and is calculated using Einstein's equation:

$$E = \Delta m c^2$$

where (Δm) is the mass defect.

8. How do nuclear reactors work?

Nuclear reactors utilize controlled nuclear fission reactions to generate energy. Key components include:

- Fuel: Usually enriched uranium or plutonium
- Moderator: Slows down neutrons to sustain chain reactions
- Control rods: Absorb neutrons to control the reaction rate
- Coolant: Transfers heat from the reactor core
- Steam generator: Produces steam to drive turbines

The fission of uranium-235 releases energy, neutrons, and fission products, which are managed carefully to produce electricity safely.

9. What are the applications of nuclear chemistry in medicine?

Nuclear chemistry plays a vital role in diagnostic imaging and therapy:

- Radioisotope imaging: Using isotopes like Technetium-99m for medical scans
- Radiotherapy: Using gamma emitters like Cobalt-60 to target cancer cells
- Tracer studies: Tracking biological processes with labeled compounds

These applications rely on understanding decay processes, half-lives, and radiation safety.

10. How are nuclear reactions balanced?

Balancing nuclear reactions involves ensuring conservation of mass number (A) and atomic number (Z):

- Sum of A and Z on reactant side = sum on product side
- Types of reactions: Fission, fusion, and transmutation follow these principles

For example:

Balancing these equations is crucial for accurate calculations and understanding reaction pathways.

Practical Applications and Calculations in Physical Nuclear Chemistry

Calculating Activity of a Radioactive Sample

Activity (A) refers to the number of decays per second and is calculated as:

$$A = \lambda N$$

where:

- N = number of radioactive nuclei
- λ = decay constant

Alternatively, activity can be expressed using the initial number of nuclei and half-life:

$$A = A_0 e^{-\lambda t}$$

This helps in quantifying the intensity of radiation emitted, which is crucial for medical, industrial, and research applications.

Determining Decay Constant from Half-Life

Given the half-life, the decay constant can be calculated as:

$$\lambda = \frac{\ln 2}{t_{1/2}}$$

For example, if a nucleus has a half-life of 10 hours:

$$\lambda = \frac{0.693}{10 \text{ hours}} = 0.0693 \text{ hour}^{-1}$$

This value is essential in decay calculations and modeling radioactive processes.

Energy Released in Nuclear Fission

The energy released per fission event is approximately 200 MeV. To calculate the total energy from a given amount of fissile material:

- Convert mass to number of nuclei using molar mass
- Multiply by energy per fission

This enables the design of nuclear reactors and understanding of

- Calculating Half-Life and Decay Constant

Question:

A certain isotope has a half-life of 10 hours. Calculate its decay constant (λ).

Answer:

The decay constant (λ) relates to the half-life ($T_{1/2}$) via the formula:

$$\lambda = \ln(2) / T_{1/2}$$

Substituting the given values:

$$\lambda = 0.693 / 10 \text{ hours} = 0.0693 \text{ hours}^{-1}$$

Implication:

This decay constant helps determine the activity and remaining quantity over time.

- Determining Remaining Quantity After a Period

Question:

If 100 grams of a radioactive isotope with a half-life of 8 hours is left after 24 hours, how much was initially present?

Solution:

Number of half-lives elapsed:

$$n = \text{total time} / \text{half-life} = 24 / 8 = 3$$

Remaining amount:

$$\text{Remaining} = \text{Initial} \times (1/2)^n$$

Given remaining = 100 g,

$$\text{Initial} = 100 \text{ g} / (1/2)^3 = 100 \text{ g} / (1/8) = 100 \text{ g} \times 8 = 800 \text{ g}$$

Answer:

Initially, 800 grams of the isotope were present.

- Mass number: 238

Alpha particle: He-4 (atomic number 2, mass 4)

Remaining nucleus:

Atomic number: $92 - 2 = 90$ (Thorium, Th)

Mass number: $238 - 4 = 234$

Balanced equation:

- U-238: 238.0508 u
- Th-234: 234.0436 u
- He-4: 4.0026 u

Solution:

Mass difference:

$\Delta m = (\text{Mass of U-238}) - (\text{Mass of Th-234} + \text{He-4})$

$= 238.0508 \text{ u} - (234.0436 \text{ u} + 4.0026 \text{ u})$

$= 238.0508 \text{ u} - 238.0462 \text{ u}$

$= 0.0046 \text{ u}$

Energy released:

$Q = \Delta m \times 931.5 \text{ MeV/u} = 0.0046 \times 931.5 = 4.28 \text{ MeV}$

Implication:

This energy is carried away by the alpha particle and recoil nucleus, critical in understanding nuclear

power.

- **First Law (Law of Inertia):** An object remains at rest or moves uniformly unless acted upon by an external force.
- **Second Law:** The acceleration of an object is directly proportional to the net force acting upon it and inversely proportional to its mass ($F = ma$).
- **Third Law:** For every action, there is an equal and opposite reaction.

Application in Life:

- Walking involves friction and muscle forces to overcome inertia.
- The functioning of joints and muscles can be explained through these laws.
- Understanding projectile motion helps in sports and medical diagnostics.

2. Energy and Its Conservation in Biological Systems

Energy transfer is vital in life processes such as muscle movement, digestion, and cellular activities.

Types of Energy:

- Kinetic Energy: Energy of moving parts (e.g., blood flow, muscle movement).
- Potential Energy: Stored energy in biological molecules.
- Mechanical Energy: Combination of kinetic and potential energy in biological motions.

Conservation of Energy:

- The total energy in an isolated system remains constant.

3. Buoyancy and Fluid Mechanics

Understanding how objects float or sink is essential in areas like medicine (e.g., hydrodynamic therapies) and marine biology.

Archimedes' Principle:

- An object submerged in a fluid experiences an upward buoyant force equal to the weight of the displaced fluid.

Mathematical Expression:

$$F_b = \rho_f \times g \times V$$

where:

- F_b = buoyant force,
- ρ_f = density of the fluid,
- g = acceleration due to gravity,
- V = volume of displaced fluid.

Applications:

- Design of submarines and ships.
- Understanding blood circulation and respiratory mechanics.

4. Optics and Its Applications in Life

Optics principles explain various biological phenomena and technological innovations.

Refraction and Reflection:

- Light bending in lenses (e.g., eyes, microscopes).
- Reflection principles in periscopes and optical devices.

Human Eye:

- The eye functions as a convex lens system.
- Corrective lenses use refraction principles to treat vision problems like myopia and hypermetropia.

Applications:

- Optical instruments in medical diagnostics.
- Fiber optics in communication.

Step-by-Step Full Solution of Typical Problems

To excel in NSS Physics in Life 2, mastering problem-solving strategies is essential. Below are detailed solutions to common types of questions.

Problem 1: Calculating the Buoyant Force

Question:

A solid sphere of volume 0.02 m^3 is submerged in water. Find the buoyant force acting on the sphere. (Density of water = 1000 kg/m^3 , $g = 9.8 \text{ m/s}^2$)

Solution:

- Identify known values:
 - Volume, $(V = 0.02 \text{ m}^3)$
 - Density of water, $(\rho_f = 1000 \text{ kg/m}^3)$
 - Gravitational acceleration, $(g = 9.8 \text{ m/s}^2)$
- Use Archimedes' principle:

$$F_b = \rho_f \times g \times V$$

- Substitute the values:

$$F_b = 1000 \times 9.8 \times 0.02$$

$$F_b = 1000 \times 0.196$$

$$F_b = 196 \text{ N}$$

Answer:

The buoyant force acting on the sphere is 196 Newtons.

Problem 2: Determining the Acceleration of an Object Under Force

Question:

A biological cell experiences a force of 0.05 N due to fluid flow. If the mass of the cell is (2×10^{-12}) kg, calculate its acceleration.

Solution:

- Known data:

- Force, $(F = 0.05 \text{ N})$

- Mass, $(m = 2 \times 10^{-12} \text{ kg})$

- Use Newton's second law:

$$[a = \frac{F}{m}]$$

- Calculation:

$$[a = \frac{0.05}{2 \times 10^{-12}}]$$

$$[a = 0.05 \div 2 \times 10^{12}]$$

$$[a = 0.025 \times 10^{12}]$$

$$[a = 2.5 \times 10^{10} \text{ m/s}^2]$$

Answer:

The cell accelerates at (2.5×10^{10}) m/s² under the given force.

Problem 3: Light Refraction and Eye Focus

Question:

An object is placed 30 cm from a convex lens of focal length 15 cm. Find the position of the image formed.

Solution:

- Known data:

- Object distance, $(u = -30 \text{ cm})$ (negative because object is on the same side as the incoming light)

- Focal length, $(f = +15 \text{ cm})$

- Use the lens formula:

$$\frac{1}{f} = \frac{1}{v} - \frac{1}{u}$$

- Rearrange to find (v) :

$$\frac{1}{v} = \frac{1}{f} + \frac{1}{u}$$

$$\frac{1}{v} = \frac{1}{15} + \frac{1}{-30}$$

$$\frac{1}{v} = \frac{2}{30} - \frac{1}{30} = \frac{1}{30}$$

- Calculate (v) :

$$v = 30 \text{ cm}$$

Interpretation:

- The positive value indicates the image is real and formed on the opposite side of the lens, at 30 cm from the lens.

λ

$$T_{1/2} = \frac{\ln 2}{\lambda}$$

\]

- Substitute the given value:

\[

$$T_{1/2} = \frac{\ln 2}{0.693} \approx 1 \text{ day}$$

Wong's Tip: Always verify units and double-check the logarithm value for accuracy.

2. Computing Nuclear Binding Energy

Problem: Given the masses:

- Proton: (1.0073 u)
- Neutron: (1.0087 u)
- Helium nucleus (${}^4\text{He}$): (4.0015 u)

Solution Approach:

- Calculate the total mass of constituent nucleons:

\[

$$(2 \times 1.0073 \text{ u}) + (2 \times 1.0087 \text{ u}) = 4.0319 \text{ u}$$

\]

- Find mass defect:

[

$$\Delta m = 4.0319 \text{ u} - 4.0015 \text{ u} = 0.0304 \text{ u}$$

]

- Convert mass defect to energy:

[

$$M_{\text{initial}} = 235.0439 \text{ u} + 1.0087 \text{ u} = 236.0526 \text{ u}$$

\\

- Calculate total final mass:

\\

$$M_{\text{final}} = 140.9144 \text{ u} + 91.9262 \text{ u} = 232.8406 \text{ u}$$

\\

- Find mass difference:

\\

$$\Delta m = 236.0526 \text{ u} - 232.8406 \text{ u} = 3.212 \text{ u}$$

\\

- Convert to energy:

$$]$$

where (λ) is the decay constant.

Step 3: Find (λ)

$$[$$

$$\frac{A}{A_0} = e^{-\lambda t} \Rightarrow \frac{100}{800} = e^{-\lambda \times 3}$$

$$]$$

$$[$$

$$\frac{1}{8} = e^{-3\lambda}$$

$$]$$

Taking natural logs:

$$[$$

$$\ln \left(\frac{1}{8} \right) = -3\lambda$$

$$\ln$$

$$\ln$$

$$-\ln 8 = -3\lambda$$

$$\ln$$

$$\ln$$

$$\lambda = \frac{\ln 8}{3}$$

$$\ln$$

Calculate:

$$\ln$$

$$\ln 8 \approx 2.0794$$

$$\ln$$

$$\ln$$

$$\lambda \approx \frac{2.0794}{3} \approx 0.6931 \, \text{hr}^{-1}$$

$$\ln$$

Step 4: Find half-life ($T_{1/2}$)

$$\ln$$

$$T_{1/2} = \frac{\ln 2}{\lambda} \approx \frac{0.6931}{0.6931} = 1 \, \text{hr}$$

$$\ln$$

Answer: The half-life of the isotope is approximately 1 hour.

2. Nuclear Reaction Calculations

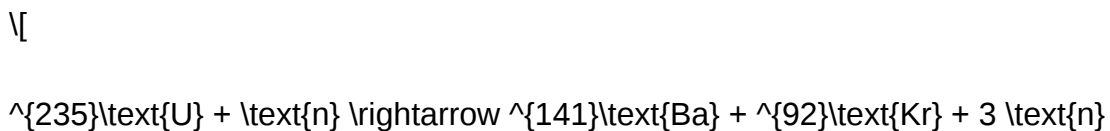

Problem Example:

Calculate the energy released when uranium-235 undergoes fission producing barium-141, krypton-92, and three neutrons. Given atomic masses:

- ^{235}U : 235.0439 u
- ^{141}Ba : 140.9144 u
- ^{92}Kr : 91.9262 u
- Neutron: 1.0087 u

Solution:

Step 1: Write the reaction

Step 2: Calculate total initial mass

$$m_{\text{initial}} = 235.0439 \text{ u} + 1.0087 \text{ u} = 236.0526 \text{ u}$$

Step 3: Calculate total final mass

$$m_{\text{final}} = 140.9144 \text{ u} + 91.9262 \text{ u} + 3 \times 1.0087 \text{ u}$$

$$= 140.9144\text{ u} + 91.9262\text{ u} + 3.0261\text{ u} = 235.8667\text{ u}$$

\\

Step 4: Find mass defect

\\

$$\Delta m = m_{\text{initial}} - m_{\text{final}} = 236.0526\text{ u} - 235.8667\text{ u} = 0.1859\text{ u}$$

\\

Step 5: Convert mass defect to energy

Using Einstein's relation $(E = \Delta m c^2)$, and knowing $1\text{ u} = 931.5\text{ MeV}/c^2$:

\\

$$E = 0.1859\text{ u} \times 931.5\text{ MeV/u} \approx 173.3\text{ MeV}$$

\\

Answer: Approximately 173.3 MeV of energy is released during the fission.

3. Binding Energy and Nuclear Stability

Problem Example:

Calculate the binding energy per nucleon for iron-56 (mass = 55.9349 u). Given atomic mass of a proton = 1.0073 u, neutron = 1.0087 u, and atomic mass of electrons is negligible for this calculation.

Solution:

Step 1: Total mass of constituent nucleons

Number of protons $(Z = 26)$, neutrons $(N = 30)$

\\

$$\text{Mass of protons} = 26 \times 1.0073\text{ u} = 26.1898\text{ u}$$

$$\]$$

$$\[$$

$$\text{Mass of neutrons} = 30 \times 1.0087 \text{ u} = 30.261 \text{ u}$$

$$\]$$

$$\[$$

$$\text{Total mass of free nucleons} = 26.1898 \text{ u} + 30.261 \text{ u} = 56.4508 \text{ u}$$

$$\]$$

Step 2: Mass defect

$$\[$$

$$\Delta m = \text{Mass of free nucleons} - \text{Mass of nucleus} = 56.4508 \text{ u} - 55.9349 \text{ u} = 0.5159 \text{ u}$$

$$\]$$

Step 3: Binding energy

$$\[$$

$$E_b = 0.5159 \text{ u} \times 931.5 \frac{\text{MeV}}{\text{u}} \approx 480.4 \text{ MeV}$$

$$\]$$

Step 4: Binding energy per nucleon

$$\[$$

$$\frac{E_b}{A} = \frac{480.4 \text{ MeV}}{56} \approx 8.58 \text{ MeV}$$

$$\]$$

Answer: The binding energy per nucleon for iron-56 is approximately 8.58 MeV, indicating high stability.

Problem Statement:

Determine the maximum penetration depth (range) of alpha particles emitted from a radioactive source in a given material, considering energy loss mechanisms.

Solution Overview:

- The solution involves applying the Bethe-Bloch formula for energy loss:

\[

$$-\frac{dE}{dx} = \frac{4\pi N_A Z z^2 e^4}{m_e v^2} \left[\ln \left(\frac{2 m_e v^2}{I} \right) - \ln (1 - \beta^2) - \beta^2 \right]$$
